Conditioning may affect independence Independence of a collection of events Two unfair coins, A, and, B. Intuitive definition:  $P(H | \text{coin, A})=0.9$ ,  $P(H | \text{coin, B})=0.1$  Information on some of the events tells choose either coin with equal probability us nothing about probabilities related to. 0.9, the remaining events 0.9, 0.1 E.g.: Coin A,  $P(H | A) = P(H)$

However, there are many patterns of "conditioning" encountered in practice which give rise to quasi-independence conditions. Explicit and precise incorporation of these into the theory is needed in order to make the most effective use of probability as a model for behavioral and physical systems. We examine two concepts of conditional independence. The first concept is quite simple, utilizing very elementary aspects of probability theory. Only algebraic operations are required to obtain

Now that we've introduced conditional probability, we can formalize the definition of independence of events and develop four simple ways to check whether two events are independent or not. We will introduce these independence checks using examples, and then summarize.
